Oncometabolite D-2-Hydroxyglutarate Inhibits ALKBH DNA Repair Enzymes and Sensitizes IDH Mutant Cells to Alkylating Agents

Highlights

- IDH mutations and 2HG inhibit the DNA repair enzyme ALKBH
- IDH mutant cells are sensitized to alkylating agents
- Alkylating chemotherapy agents should be explored for treating IDH-mutated tumors

In Brief

Wang et al. demonstrate that D-2-HG produced by mutant IDH inhibits alkylated DNA repair enzymes, leading to DNA damage and sensitizing IDH mutant cells to alkylating agents. These results suggest that impairment of DNA repair may contribute to tumorigenesis driven by IDH mutations and that alkylating agents should be explored as a therapeutic option for IDH-mutated cancer patients.

SUMMARY

Chemotherapy of a combination of DNA alkylating agents, procarbazine and lomustine (CCNU), and a microtubule poison, vincristine, offers a significant benefit to a subset of glioma patients. The benefit of this regimen, known as PCV, was recently linked to IDH mutation that occurs frequently in glioma and produces D-2-hydroxyglutarate (D-2-HG), a competitive inhibitor of α-ketoglutarate (α-KG), also known as 2-oxoglutarate), and gain of a neomorphic activity, the reduction of α-KG to D-2-hydroxyglutarate (D-2-HG) (Dang et al., 2009; Yan et al., 2009; Zhao et al., 2009). D-2-HG is structurally similar to α-KG and acts as an antagonist of α-KG to competitively inhibit multiple α-KG-dependent dioxygenases, including the JmjC domain-containing histone demethylases (KDMs) and the TET (ten-eleven translocation) family of DNA hydroxylases (Chowdhury et al., 2011; Xu et al., 2011). Altered epigenetic regulation is currently considered to be a major mechanism whereby IDH mutation and D-2-HG exert their oncogenic effects.

INTRODUCTION

Genes encoding for isocitrate dehydrogenases 1 and 2, IDH1 and IDH2, are frequently mutated in grade II and grade III anaplastic oligodendrogliomas (AOA), mixed oligoastrocytomas and astrocytomas, and WHO grade IV secondary glioblastomas (GBMs) (>75%) (Parsons et al., 2008) as well as several other types of human cancer, including acute myeloid leukemia (AML, ~20%), cartilaginous tumors (75%), intrathoracic cholangiocarcinomas (10%–23%), angioimmunoblastic T cell lymphoma (AITLs, ~20%), and melanoma (~5%) (reviewed by Cairns and Mak, 2013; Yang et al., 2012). Tumor-derived IDH1 and IDH2 mutations simultaneously cause loss of its normal activity, the production of α-ketoglutarate (α-KG, also known as 2-oxoglutarate), and gain of a neomorphic activity, the reduction of α-KG to D-2-hydroxyglutarate (D-2-HG) (Dang et al., 2009; Yan et al., 2009; Zhao et al., 2009). D-2-HG is structurally similar to α-KG and acts as an antagonist of α-KG to competitively inhibit multiple α-KG-dependent dioxygenases, including the JmjC domain-containing histone demethylases (KDMs) and the TET (ten-eleven translocation) family of DNA hydroxylases (Chowdhury et al., 2011; Xu et al., 2011). Altered epigenetic regulation is currently considered to be a major mechanism whereby IDH mutation and D-2-HG exert their oncogenic effects.

The unique property of mutant IDH1/2 in producing an oncometabolite that has no known physiological function makes mutant IDH enzymes as obvious potential therapeutic targets for the treatment of IDH-mutated tumors (Rohle et al., 2013; Wang et al., 2013). Clinical studies have also suggested the presence of a sequela target(s) for treating IDH-mutated gliomas. Following an early study showing successful chemotherapy for recurrent malignant oligodendroglioma (Cairncross and Macdonald, 1988), randomized controlled trials were carried out in both the North America (RTOG 9402) and Europe (EORTC 26951). These studies have shown clear benefits for both anaplastic oligodendroglioma (AO) and oligoastrocytoma (AOA) patients who in addition to radiation therapy received chemotherapy of procarbazine, CCNU/lomustine, and vincristine (PCV) (Cairncross et al., 2013, 2014; Erdem-Eraslan et al., 2013; van den Bent et al., 2013). PCV benefit was recently linked to IDH1 mutations with an overall survival of 9.4 years for IDH1-mutated patients versus 5.7 years for patients with wild-type IDH (Cairncross et al., 2014). Of three agents in PCV regimen, vincristine inhibits microtubule assembly, and CCNU and procarbazine are DNA alkylating agents. The molecular mechanism(s) underlying the therapeutic benefits that are conferred by PCV is not known and is investigated in this study.
RESULTS

D-2-HG Inhibits ALKBH Enzymes In Vitro

Endogenous (e.g., S-adenosylmethionine, SAM) and environmental (e.g., nitrosoureas) alkylating agents cause methylated bases in DNA that can be mutagenic and cytotoxic if not repaired. The major enzymes repairing the methylated lesions such as 1-methyladenine (1meA) and 3-methylcytosine (3meC) are the AlkB proteins. Like the JmjC KDMs and TET proteins, AlkB belongs to the Fe(II)- and a-KG-dependent dioxygenases (Falnes et al., 2002) and includes nine distinct genes in human cells (AlkB homolog ALKBH1 to ALKBH8 and FTO) (Sedgwick et al., 2007). The function in repairing DNA alkylation has been demonstrated biochemically in vitro and supported by the genetic analysis of mutant mice for mammalian ALKBH2 and ALKBH3 (Aas et al., 2003; Dango et al., 2011; Duncan et al., 2002; Lee et al., 2005; Ringvoll et al., 2006). We therefore examined the effect of D-2-HG on the activity of ALKBH2 and ALKBH3 using purified recombinant ALKBH2 and ALKBH3 proteins and DNA oligo containing 1-methyldeoxyadenosine (1MedA) (Figure S1A). We found that purified ALKBH2 and ALKBH3 rapidly (within 1 min) demethylated (repaired) methylated adenine (Figure S1B). Addition of 0.5 mM D-2-HG resulted in nearly 50% inhibition of ALKBH2 (Figure S1C). This is consistent with a previous observation, showing that D-2-HG inhibits DNA repair enzyme ALKBH2 in vitro, with an IC50 value of 0.424 mM (Chowdhury et al., 2011). Similarly, ALKBH3 rapidly (within 1 min) repaired methyl-adenine, a reaction that was also inhibited by D-2-HG (Figure 1A). Although D-2-HG is a relatively weak inhibitor of ALKBH2 and ALKBH3 and may not have significant effect on ALKBH-mediated repair under normal physiological conditions, the high levels of D-2-HG that accumulate in IDH-mutated gliomas (i.e., 5–35 mmol/l in glioma [Dang et al., 2009]) suggest that it could significantly impair the ALKBH function in IDH-mutated cells, like other a-KG-dependent dioxygenases reported to be inhibited by 2-HG (Table S1).

2-HG Inhibits Removal of Alkylating Agent Induced DNA Damages in Glioma Cells

To investigate whether ALKBH2 and ALKBH3 could be inhibited by 2-HG, we established U87-MG glioma stable cell lines expressing wild-type or R132H mutant IDH1 at a level similar to that of endogenous IDH1 (Figure 1B). These stable cells were treated with 2 mM methyl methanesulfonate (MMS), which generates 1-methyldeoxyadenosine (1MedA), which generates 1-methyldeoxyadenosine (1MedA). Expression of mutant IDH1 significantly delayed the repair kinetics, resulting in 7-fold increase in the half-life of 1MedA in genomic DNA from 0.52 hr in cells expressing wild-type IDH1 to 3.67 hr in cells expressing R132H mutant IDH1. Unrepaired DNA adduct would cause DNA double-strand breaks (DSBs). Consistently, when compared with cells expressing wild-type IDH1, both U87-MG and U373-MG cells expressing R132H mutant IDH1 exhibited substantially increased DSBs after MMS treatment, as determined by both western blot and immunofluorescence using an antibody to phosphorylated histone variant H2AX (γ-H2AX, Figures 1C–1E and S1D). Moreover, qRT-PCR analysis showed that multiple genes from different DNA repair pathways were significantly (p < 0.05) upregulated in cells expressing mutant IDH1 when compared to control cells expressing wild-type IDH1 (Figure S1E). The endogenous protein levels of neither ALKBH2 nor ALKBH3 were affected by the expression of either wild-type or mutant IDH1 (Figure S1F). Although IDH1 mutant sensitizes cells to alkylating agents, cells expressing wild-type or mutant IDH1 responded to ultraviolet (UV) light and ionizing radiation (IR) similarly (Figure S1G). Together, these results demonstrate that tumor-derived mutant IDH1 inhibits the activity of ALKBH enzymes and results in the accumulation of DNA damages in cells exposure to alkylating agents.

Expression of Tumor-Derived IDH1 Mutant Sensitizes Cells to Alkylating Agents

E. coli alkB mutants are sensitive to killing by alkylating agents such as MMS, especially during exponentially doubling (Dinglay et al., 2000; Kataoka et al., 1983). This defect can be rescued by the expression of human ALKBH2 and ALKBH3 (Dinglay et al., 2000; Duncan et al., 2002). The finding that D-2-HG inhibits ALKBH2 and ALKBH3 led us to test whether cultured human cells expressing mutant IDH1 are sensitized to alkylating agents. We exposed both U87-MG and U373-MG glioblastoma cells stably expressing wild-type or R132H mutant IDH1 to N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) or MMS. Cell death and viability were then assessed by flow cytometry analysis (Figure 2A), MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay (Figure 2B), and trypan blue exclusion (Figure 2C). Consistently seen in all three assays, either MNNG or MMS treatment decreased cell viability in a dose-dependent manner in both cell lines but had more significant (p < 0.05) killing effects in cells expressing mutant IDH1 compared to cells expressing wild-type IDH1. Fluorescence-activated cell sorting (FACS) analysis revealed that treatments with 4 and 5 mM MMS resulted in 36.1% and 61.4% Annexin-PI double-positive cells, respectively, in cells expressing R132H mutant, significantly higher than the cells expressing wild-type IDH1 (20.9% and 42.3%, respectively, Figure S2). Knockdown ALKBH2 with
two different shRNAs in MMS-treated cells increased the death of U87-MG (wild-type IDH1) cells (Figure 2D), indicating a role of ALKBH2 in protecting U87-MG cells from MMS-induced death. In contrast, depletion of ALKBH2 did not synergistically increase MMS-induced cell death in U87-MG (IDH1 R132H) cells. This result is consistent with the notion that the activity of ALKBH2 in protecting MMS-induced cell death requires the α-KG-dependent catalytic function that is inhibited by the high level of D-2-HG accumulated in the U87-MG (IDH1R132H) cells.

Alkylating Agents Sensitizing Effect of Mutant IDH1 Is Dependent on 2-HG and Can Be Partially Reduced by Overexpression of ALKBH2 and ALKBH3

To determine directly whether the sensitization to alkylating agents by IDH1 mutation is dependent on 2-HG, we introduced a second mutation into the D-2-HG-producing IDH1 R132H mutant to disrupt its binding to α-KG, which is required for the production of D-2-HG through the NADPH-dependent reduction of α-KG (Dang et al., 2009). Six IDH1 double mutants, R132H/T77A, R132H/S94A, R132H/N96A, R132H/Y139A, R132H/K212Q, and R132H/T214A were identified whose catalytic activity to produce D-2-HG was markedly reduced (Figures 3A and 3B). We then established U87-MG cells stably expressing IDH1, IDH1 R132H, IDH1 R132H/T77A, or IDH1 R132H/S94A (Figure S3A) and exposed these stable cells to different concentrations of MMS or MNNG. We observed that the sensitization to MMS and MNNG, conferred by R132H mutant IDH1, was completely abolished by second mutations that eliminated 2-HG production (Figure 3C). Supporting this conclusion, disruption of 2HG-producing activity also hinders the activation of DNA repair genes by the mutant IDH1 (Figures S3B and 3D).

HT1080 fibrosarcoma cells carry heterozygous R132C mutation in IDH1 (IDH1 +/R132C) (Amary et al., 2011). We deleted the R132C mutant allele from HT1080 by TALEN technique and

generated the IDH1**+/−** cell line (Ma et al., 2015). GC-MS analysis confirmed that 2-HG was produced in the parental IDH1**+/+R132C** cells but was not detectable in the IDH1**+/−** cells (Figure 3E). We found that deletion of the R132C mutant allele reduced the sensitivity of HT1080 cells to both MMS and MNNG alkylating agents (Figure 3F). We next stably overexpressed ALKBH2 or ALKBH3 in IDH1**+/+R132C** and IDH1**+/−** HT1080 cells by retrovirus transduction (Figure 3G). We found that overexpression of either ALKBH partially rescued the sensitivity in parental IDH1**+/+R132C** cells, but not in the IDH1**+/−** cells, to MMS treatment (Figure 3H).

Taken together, we conclude that the ability of mutant IDH1 to sensitize cells to DNA alkylating agents is dependent on its catalytic activity to produce 2-HG.

**Mutant IDH1 Sensitizes Cells to Therapeutic Alkylating Drugs**

To explore the potential clinical significance of sensitizing effects by mutant IDH to alkylating agents, we examined the responses of cells expressing either wild-type or mutant IDH1 to busulfan, an alkylator that has commonly been used to treat chronic myeloid leukemia (CML) before the advent of imatinib. We found that U87-MG cells expressing R132H mutant IDH1 were significantly more sensitive to busulfan than control cells expressing wild-type IDH1, and that the enhanced sensitivity was completely abolished by the mutations disrupting D-2-HG production (Figure 4A).

Of three agents in PCV regimen, vincristine inhibits microtubule assembly, and CCNU and procarbazine are DNA alkylating agents. We found that the expression of R132H mutant IDH1 in U87-MG cells caused significant sensitivity to CCNU compared with the expression of wild-type IDH1 (Figure 4B). In contrast, treatment of cell with vincristine, while effectively reduced cell viability, exhibited indistinguishable effect toward cells expressing either the wild-type or mutant IDH1. Moreover, compared to cells treated with CCNU alone, combined exposure to CCNU and procarbazine or CCNU and vincristine had no additive or synergistic effect on the killing of cells expressing mutant or wild-type IDH1 (Figure 4C). Furthermore, overexpression of either ALKBH2 or ALKBH3 partially reduced the death HT1080 cells exposed to CCNU (Figure 4D), supporting the notion that IDH1 mutation and 2-HG accumulation sensitize HT1080 cells to CCNU by inhibiting the activity of ALKBH. The rescue by overexpressed ALKBH did not reach complete, likely due to the high levels of 2-HG accumulated in the cells. These results provide a plausible molecular explanation for the link between PCV benefit and IDH mutation observed in the clinical trials. The interpretation of lack of sensitizing effect by IDH mutation to procarbazine needs to be cautious as procarbazine becomes active only after it is metabolized by cytochrome p450 and monoamine oxidase, mainly in the liver (Weinkam and Shiba, 1978), and works poorly in non-hepatic cells lacking high oxidase activity (Swaffar et al., 1989).

**DISCUSSION**

This study provides two insights into the IDH mutation. First, our results suggest a mechanism by which IDH mutation contributes to tumorigenesis. There is strong evidence that IDH1/2 mutations alter epigenetic regulation in affected cells (Chowdary et al., 2011; Figueroa et al., 2010; Noshmehr et al., 2010; Sasaki et al., 2012; Xu et al., 2011). We show in this study that in addition to altering epigenetic control, impairment of DNA repair may also contribute to tumorigenesis driven by IDH mutation. Second, the results presented here implicate a targeted therapy for treating patients with IDH1/2-mutated tumors. As demonstrated in this study, glioma cells or chondrosarcoma cells with expression of mutant IDH1 are significantly more sensitive to MNNG, MMS, busulfan, and CCNU, compared to cells expressing only wild-type IDH1, suggesting that the classical alkylating agents may be an appropriate and “targeted” therapy for patients with IDH1/2-mutated cancers. This hypothesis is supported by the results of the aforementioned trials showing that four to six cycles of PCV were sufficient with RT to double the survival of patients with AO and AOA (Cairncross et al., 2013; Erdem-Eraslan et al., 2013; van den Bent et al., 2013). The PCV benefit was recently linked to IDH1 mutation (Cairncross et al., 2014). Our study provides a molecular basis for the PCV benefit linked to IDH mutation. Our finding that IDH1 mutation and 2HG accumulation sensitize cells to CCNU also suggests that whether future inhibitor targeting mutant IDH and blocking the D-2HG production should be used in combination with PCV need to be investigated.

**Figure 3. Alkylating Agents Sensitizing Effect of Mutant IDH1 is Dependent on 2-HG**

(A and B) Characterization of 2-HG producing activity of IDH1 double mutants. The activity of various IDH1 double mutants in producing 2-HG was determined by both the ratio of NADPH oxidation (A) and GC-MS analysis (B). Peaks at 19.6 min were identified as bis-TBDMDS-derived 2-HG by the mass fragment spectra. The bis-TBDMDS 2-HG-specific 433-m/z fragment is shown in the insert. Moreover, the peaks at 18.5 and 20.3 min were identified as the derivatives of aspartate (Asp) and glutamate (Glu), respectively. **p < 0.01 by Student’s t test between IDH1**+/+R132C** and IDH1**+/−**.

(C) U87-MG cells stably expressing the indicated proteins were exposed to increasing concentrations of MNNG or MMS. Cell death was assessed by performing flow cytometry analysis and trypan blue staining for viable cell counting.

(D) The miRNA expression of selected DNA repair genes was tested in U87-MG cells stably expressing the indicated proteins, as determined by qRT-PCR analysis.

(E) HT1080 (IDH1**+/−**) cell line was generated by knocking out the R132C allele in parental HT1080 (IDH1**+/+R132C**) cells using TALEN technique. Metabolites extracted from HT1080 (IDH1**+/−**) and parental HT1080 (IDH1**+/+R132C**) cells were subjected to GC-MS analysis, showing the loss of 2-HG accumulation in HT1080 (IDH1**+/−**) cells.

(F) HT1080 (IDH1**+/−**) and parental HT1080 (IDH1**+/+R132C**) cells were exposed to increased concentrations of MNNG or MMS. Cell death was assessed by performing flow cytometry analysis and trypan blue staining for viable cell counting. Shown are average values of triplicated results with SD. **p < 0.05 for HT1080 (IDH1**+/−**) versus parental HT1080 (IDH1**+/+R132C**) cells.

(G and H) Parental HT1080 (IDH1**+/+R132C**) and TALEN-edited HT1080 (IDH1**+/−**) cells stably expressing FLAG tagged ALKBH2 or ALKBH3 were established by retrovirus transduction. Expression of ALKBH was verified by western blot (G). The sensitivity of both IDH1**+/+R132C** and IDH1**+/−** cells to MMS was determined by MTT assay (H).
(legend on next page)
In addition to glioma, IDH1 and IDH2 mutations also occur at high frequency in several other types of human malignancies. There is no obvious reason that sensitization to DNA alkylating agents conferred by mutant IDH and D-2-HG is unique to glioma. We have demonstrated in this study that chondrosarcoma cells harboring IDH1 mutation are sensitive to alkylating agent in a manner that is dependent on the mutant IDH1. A number of FDA-approved DNA alkylating agents, such as CCNU and busulfan, have long been used in clinical for cancer treatment. They may merit for further exploration for treatment of other IDH-mutated tumors.

EXPERIMENTAL PROCEDURES

Please refer to Supplemental Experimental Procedures for more detailed information about procedures for protein expression and purification; in vitro ALKBH2 and ALKBH3 activity assay; cell culture, treatment, transfection, viability assay; metabolite extraction and LC-MS/MS analysis of nucleosides.

Antibodies, Plasmids, and Chemicals

Antibodies against Flag (ShanghaiGenomics), β-actin (Genescript), H2AX (Sigma-Aldrich), IDH1, ALKBH2, ALKBH3 (Epitomics), and phosphor-γ-H2AX (Santa Cruz Biotechnology) were purchased commercially. ALKBH2 and ALKBH3 cDNAs were kind gifts from the Han Jiahua’s Lab, Xiamen University and subcloned into pEGFP for the expression and purification in E. coli. Wild-type and mutant IDH1 was constructed into pcDNA3.1 for transient expression or pBABE-puro for stable transduction by retrovirus. ALKBH2 and ALKBH3 were constructed into pBabe-hygro for stable transduction. shRNAs targeting ALKBH2 are cloned into pLKO.1, and the sequence is listed in Table S2.

MNNG (Tokyo Chemical Industry, TCI), MMS (Sigma-Aldrich), Temozolomide (TCl), busulfan (TCl), procarbazine/CCNU (Selleckchem), and vincristine (Selleckchem) were purchased commercially.

RNA isolation and qRT-PCR Analysis

Total RNA was isolated from cultured cells using Trizol reagent (Invitrogen) following the manufacturer’s instructions. RNA was reversely transcribed in the presence of SYBR Premix Ex Taq (TaKaRa). Primer sequences are listed in Table S2.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Supplemental Experimental Procedures, three figures, and two tables and can be found with this article online at http://dx.doi.org/10.1016/j.crep.2015.11.029.

AUTHOR CONTRIBUTIONS

Most of the experiments were done by P.W. and designed by Y.X., D.Y., K.-L.G., P.W., J.W., K.A.H., M.D.W., and C.M.P. The manuscript was written by K.-L.G. and J.W. S.M. provided IDH1 knockout HT1080 cells. L.Z. and J.Y. did the LC/MS/MS analysis.
